## Self-Attention and Transformers <sup>1</sup>

**Instruction:** Please submit a pdf file named **written.pdf** via LMS. All work must be written in **English**.

Multi-head self-attention is the core modeling component of Transformers. In this question, we'll get some practice working with the self-attention equations, and motivate why multi-headed self-attention can be preferable to single-headed self-attention.

Recall that attention can be viewed as an operation on a *query* vector  $q \in \mathbb{R}^d$ , a set of *value* vectors  $\{v_1, \dots, v_n\}, v_i \in \mathbb{R}^d$ , and a set of *key* vectors  $\{k_1, \dots, k_n\}, k_i \in \mathbb{R}^d$ , specified as follows:

$$c = \sum_{i=1}^n v_i \alpha_i \quad (1)$$

$$\alpha_i = \frac{\exp(k_i^\top q)}{\sum_{j=1}^n \exp(k_j^\top q)} \quad (2)$$

with  $\alpha = \{\alpha_1, \dots, \alpha_n\}$  termed the “attention weights”. Observe that the output  $c \in \mathbb{R}^d$  is an average over the value vectors weighted with respect to  $\alpha$ .

- (a) **Copying in attention.** One advantage of attention is that it's particularly easy to “copy” a value vector to the output  $c$ . In this problem, we'll motivate why this is the case.
- Explain** why  $\alpha$  can be interpreted as a categorical probability distribution.
  - The distribution  $\alpha$  is typically relatively “diffuse”; the probability mass is spread out between many different  $\alpha_i$ . However, this is not always the case. **Describe** (in one sentence) under what conditions the categorical distribution  $\alpha$  puts almost all of its weight on some  $\alpha_j$ , where  $j \in \{1, \dots, n\}$  (i.e.  $\alpha_j \gg \sum_{i \neq j} \alpha_i$ ). What must be true about the query  $q$  and/or the keys  $\{k_1, \dots, k_n\}$ ?
  - Under the conditions you gave in (ii), **describe** the output  $c$ .
  - Explain** (in two sentences or fewer) what your answer to (ii) and (iii) means intuitively.
- (b) **An average of two.** Instead of focusing on just one vector  $v_j$ , a Transformer model might want to incorporate information from *multiple* source vectors. Consider the case where we instead want to incorporate information from **two** vectors  $v_a$  and  $v_b$ , with corresponding key vectors  $k_a$  and  $k_b$ .

---

<sup>1</sup>This homework is adapted from Stanford CS224N.

- i. How should we combine two  $d$ -dimensional vectors  $v_a, v_b$  into one output vector  $c$  in a way that preserves information from both vectors? In machine learning, one common way to do so is to take the average:  $c = \frac{1}{2}(v_a + v_b)$ . It might seem hard to extract information about the original vectors  $v_a$  and  $v_b$  from the resulting  $c$ , but under certain conditions, one can do so. In this problem, we'll see why this is the case.

Suppose that although we don't know  $v_a$  or  $v_b$ , we do know that  $v_a$  lies in a subspace  $A$  formed by the  $m$  basis vectors  $\{a_1, a_2, \dots, a_m\}$ , while  $v_b$  lies in a subspace  $B$  formed by the  $p$  basis vectors  $\{b_1, b_2, \dots, b_p\}$ . (This means that any  $v_a$  can be expressed as a linear combination of its basis vectors, as can  $v_b$ . All basis vectors have norm 1 and are orthogonal to each other.) Additionally, suppose that the two subspaces are orthogonal; i.e.  $a_j^\top b_k = 0$  for all  $j, k$ .

Using the basis vectors  $\{a_1, a_2, \dots, a_m\}$ , construct a matrix  $M$  such that for arbitrary vectors  $v_a \in A$  and  $v_b \in B$ , we can use  $M$  to extract  $v_a$  from the sum vector  $s = v_a + v_b$ . In other words, we want to construct  $M$  such that for any  $v_a, v_b$ ,  $Ms = v_a$ . Show that  $Ms = v_a$  holds for your  $M$ .

**Hint:** Given that the vectors  $\{a_1, a_2, \dots, a_m\}$  are both *orthogonal* and *form a basis* for  $v_a$ , we know that there exist some  $c_1, c_2, \dots, c_m$  such that  $v_a = c_1 a_1 + c_2 a_2 + \dots + c_m a_m$ . Can you create a vector of these weights  $c$ ?

- ii. As before, let  $v_a$  and  $v_b$  be two value vectors corresponding to key vectors  $k_a$  and  $k_b$ , respectively. Assume that (1) all key vectors are orthogonal, so  $k_i^\top k_j = 0$  for all  $i \neq j$ ; and (2) all key vectors have norm 1.<sup>1</sup> **Find an expression** for a query vector  $q$  such that  $c \approx \frac{1}{2}(v_a + v_b)$ , and justify your answer.<sup>2</sup>
- (c) **Drawbacks of single-headed attention:** In the previous part, we saw how it was *possible* for single-headed attention to focus equally on two values. The same concept could easily be extended to any subset of values. In this question, we'll see why it's not a *practical* solution. Consider a set of key vectors  $\{k_1, \dots, k_n\}$  that are now randomly sampled,  $k_i \sim \mathcal{N}(\mu_i, \Sigma_i)$ , where the means  $\mu_i \in \mathbb{R}^d$  are known to you, but the covariances  $\Sigma_i$  are unknown. Further, assume that the means  $\mu_i$  are all perpendicular;  $\mu_i^\top \mu_j = 0$  if  $i \neq j$ , and unit norm,  $\|\mu_i\| = 1$ .
- i. Assume that the covariance matrices are  $\Sigma_i = \alpha I, \forall i \in \{1, 2, \dots, n\}$ , for vanishingly small  $\alpha$ . Design a query  $q$  in terms of the  $\mu_i$  such that as before,  $c \approx \frac{1}{2}(v_a + v_b)$ , and provide a brief argument as to why it works.
- ii. Though single-headed attention is resistant to small perturbations in the keys, some types of larger perturbations may pose a bigger issue. Specifically, in some cases, one key vector  $k_a$  may be larger or smaller in norm than the others, while still

<sup>1</sup>Recall that a vector  $x$  has norm 1 if  $x^\top x = 1$ .

<sup>2</sup>Hint: while the softmax function will never *exactly* average the two vectors, you can get close by using a large scalar multiple in the expression.

pointing in the same direction as  $\mu_a$ . As an example, let us consider a covariance for item  $a$  as  $\Sigma_a = \alpha I + \frac{1}{2}(\mu_a \mu_a^\top)$  for vanishingly small  $\alpha$  (as shown in figure 1). This causes  $k_a$  to point in roughly the same direction as  $\mu_a$ , but with large variances in magnitude. Further, let  $\Sigma_i = \alpha I$  for all  $i \neq a$ .

Figure 1: The vector  $\mu_a$  (shown here in 2D as an example), with the range of possible values of  $k_a$  shown in red. As mentioned previously,  $k_a$  points in roughly the same direction as  $\mu_a$ , but may have larger or smaller magnitude.

When you sample  $\{k_1, \dots, k_n\}$  multiple times, and use the  $q$  vector that you defined in part i., what do you expect the vector  $c$  will look like qualitatively for different samples? Think about how it differs from part (i) and how  $c$ 's variance would be affected.

- (d) **Benefits of multi-headed attention:** Now we'll see some of the power of multi-headed attention. We'll consider a simple version of multi-headed attention which is identical to single-headed self-attention as we've presented it in this homework, except two query vectors ( $q_1$  and  $q_2$ ) are defined, which leads to a pair of vectors ( $c_1$  and  $c_2$ ), each the output of single-headed attention given its respective query vector. The final output of the multi-headed attention is their average,  $\frac{1}{2}(c_1 + c_2)$ . As in question 1 (c), consider a set of key vectors  $\{k_1, \dots, k_n\}$  that are randomly sampled,  $k_i \sim \mathcal{N}(\mu_i, \Sigma_i)$ , where the means  $\mu_i$  are known to you, but the covariances  $\Sigma_i$  are unknown. Also as before, assume that the means  $\mu_i$  are mutually orthogonal;  $\mu_i^\top \mu_j = 0$  if  $i \neq j$ , and unit norm,  $\|\mu_i\| = 1$ .

- i. Assume that the covariance matrices are  $\Sigma_i = \alpha I$ , for vanishingly small  $\alpha$ . Design  $q_1$  and  $q_2$  such that  $c$  is approximately equal to  $\frac{1}{2}(v_a + v_b)$ . Note that  $q_1$  and  $q_2$  should have different expressions.
- ii. Assume that the covariance matrices are  $\Sigma_a = \alpha I + \frac{1}{2}(\mu_a \mu_a^\top)$  for vanishingly small  $\alpha$ , and  $\Sigma_i = \alpha I$  for all  $i \neq a$ . Take the query vectors  $q_1$  and  $q_2$  that you designed in part i. What, qualitatively, do you expect the output  $c$  to look like across different samples of the key vectors? Explain briefly in terms of variance in  $c_1$  and  $c_2$ . You can ignore cases in which  $k_a^\top q_i < 0$ .
